Improved SWx Monitoring

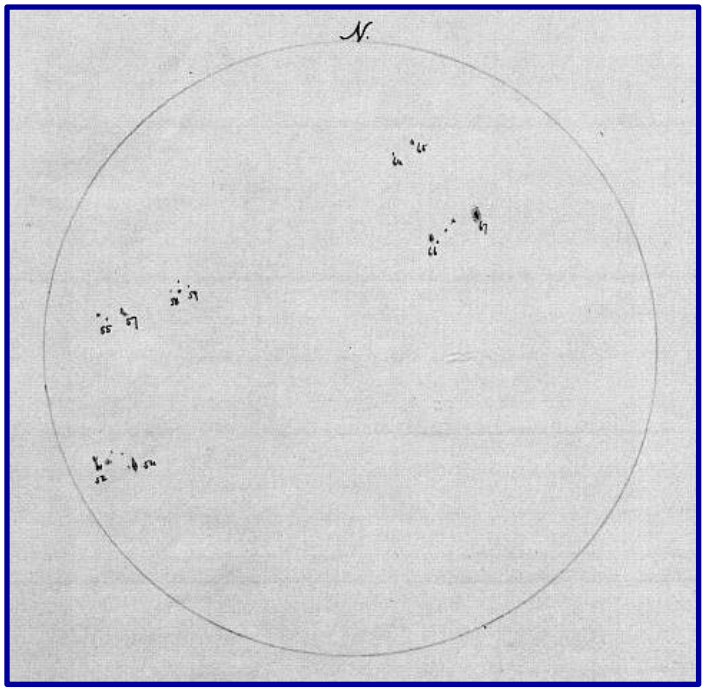
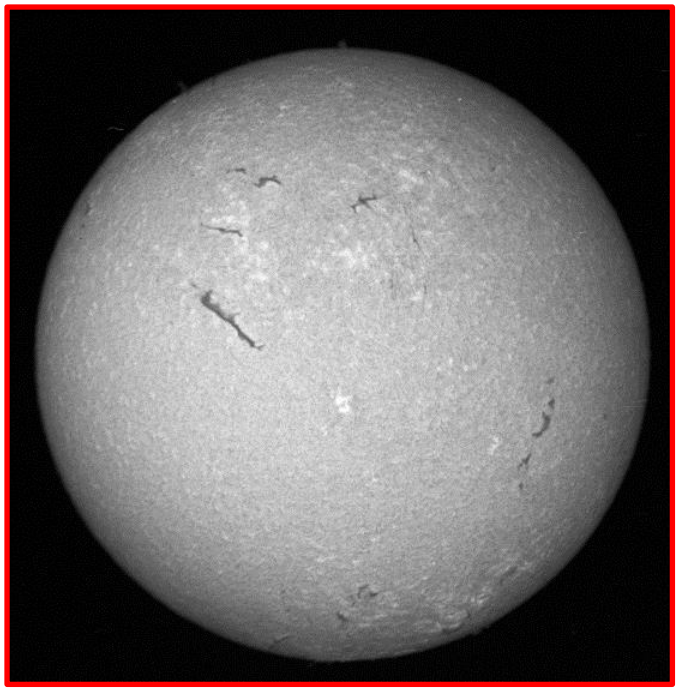
NOAA Historical Solar Observations



Observations of sunspots in white light made by Charles Anthony Schott of the Coast Survey, 1859-1860. White-light observations are of the solar photosphere. The daily sunspot number (SSN) has been a consistent solar index from the early 1800's to present.



From 1967 to 1994 the NOAA Space Environment Center observed the sun in H-alpha (656.3 nm). Chromospheric observations of prominences, filaments, plague and the chromospheric network. The USAF continues to make daily observations.

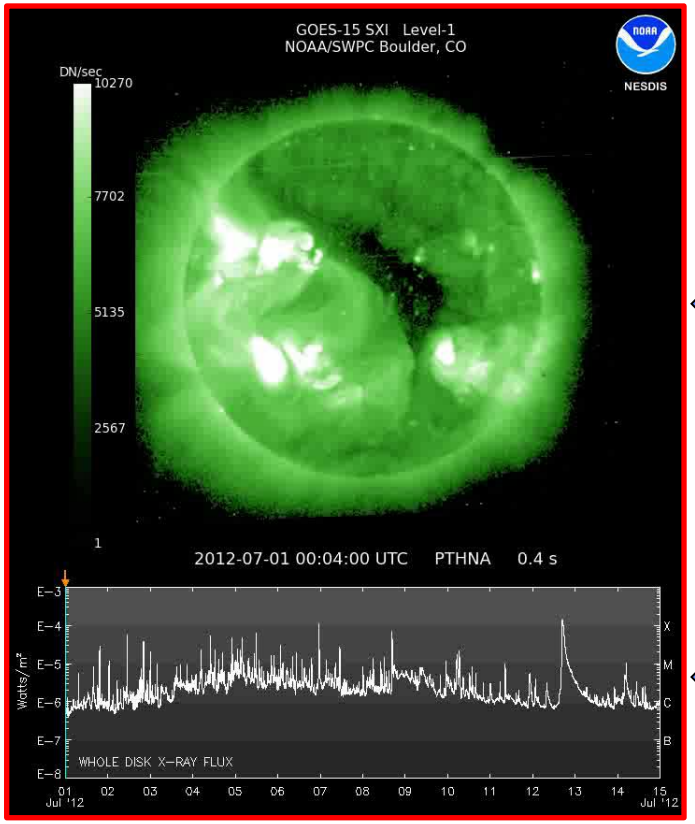
GOES Solar Imagery

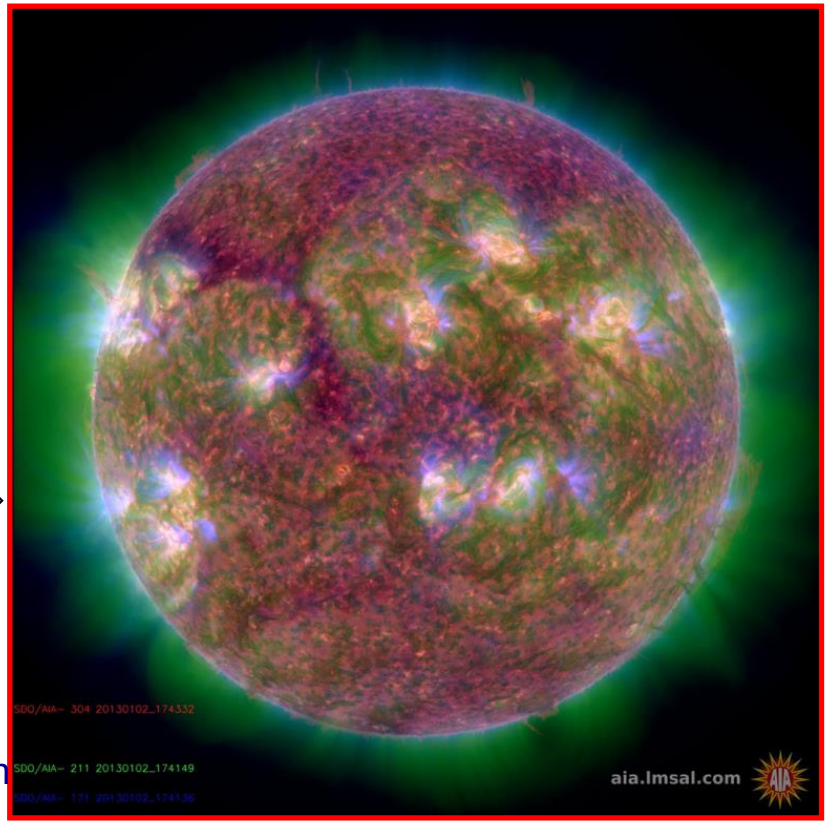


SXI

XRS

Flare Classification

AIA



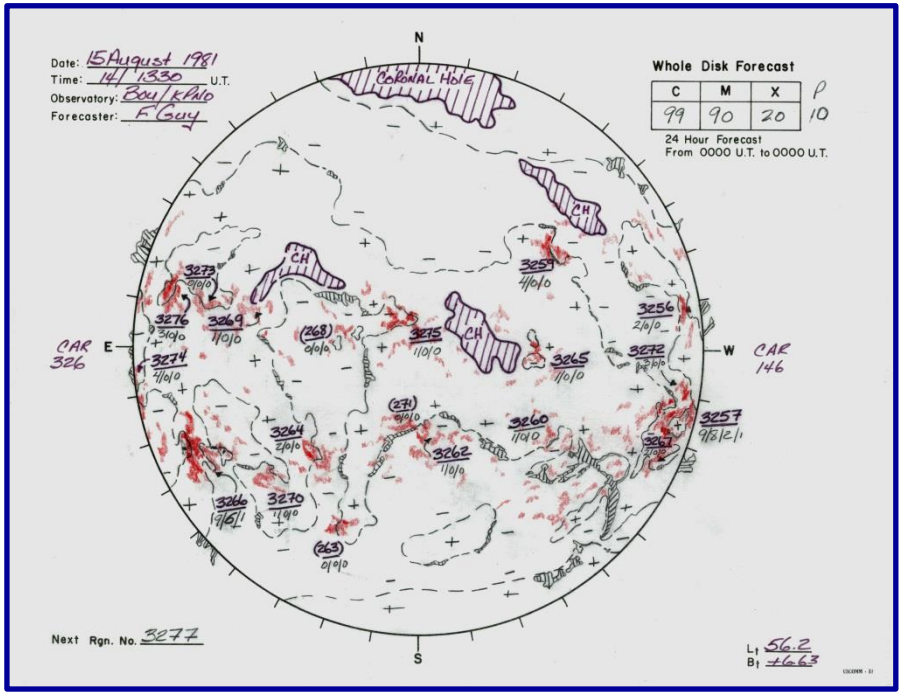
The GOES 12 through 15 spacecraft each carry a sophisticated Solar X-ray Imager (SXI) to monitor the Sun's X-rays for the early detection of solar flares, coronal mass ejections, and other phenomena that impact the geospace environment.

Heritage sensor for the Solar Ultra-Violet Imager (SUVI) is the SDO Atmospheric Imaging Assembly. Various filters of SUVI monitor the solar chromosphere, corona, and the transition region.

Improved SWx Monitoring

NOAA Daily Solar Synoptic Drawings

Each day the NOAA Space Weather Prediction Center (SWPC) produces a synoptic drawing highlighting solar areas of interest to space weather. Data for these drawings are assembled from a variety of ground-based and space sources. Future SUVI observations will provide much of the details needed by SWx operators (see slide #13)

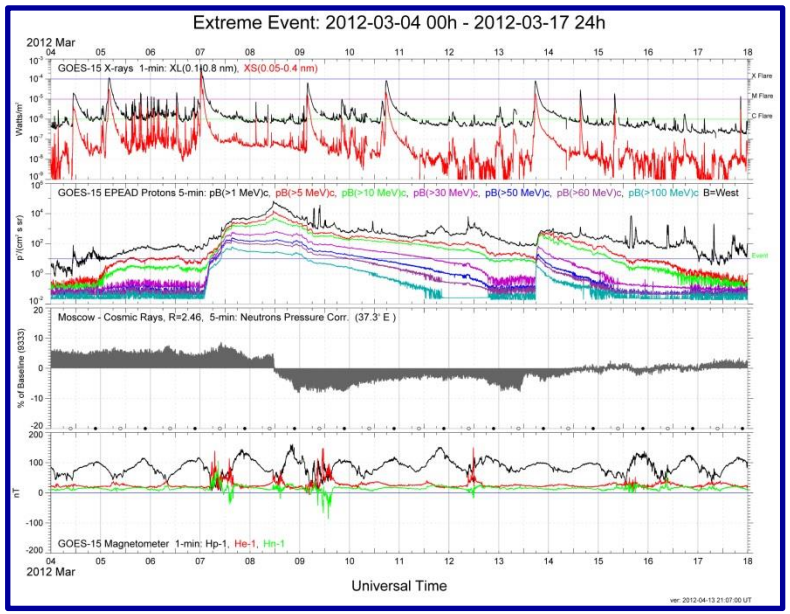


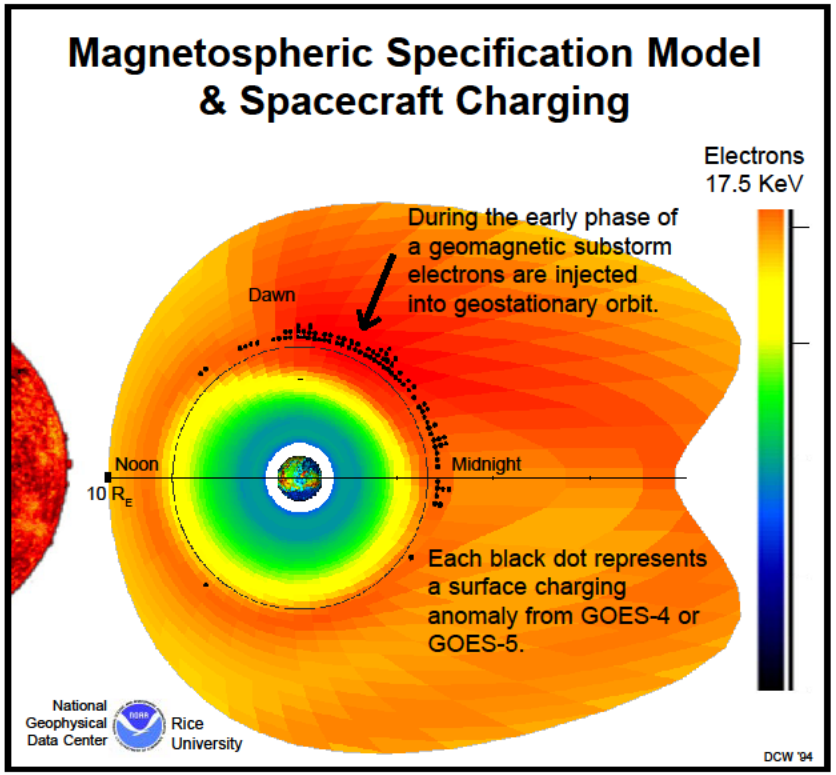
Solar synoptic maps identify features such as neutral lines, coronal hole boundaries, active regions, plage, filaments and prominences. Also included is information about the coronal hole polarity, active region numbers, flare probabilities for each region and the proton event probabilities for each region.

Improved SWx Monitoring
GOES Space Environment Monitor

"My God, Space is Radioactive!"

In 1958 Dr James Van Allen discovered that the near-earth space environment was populated by energetic charged particles. NOAA has continually monitored the space environment since 1974. The early GOES-4 and -5 spacecraft experienced numerous anomalies due to space particle effects.





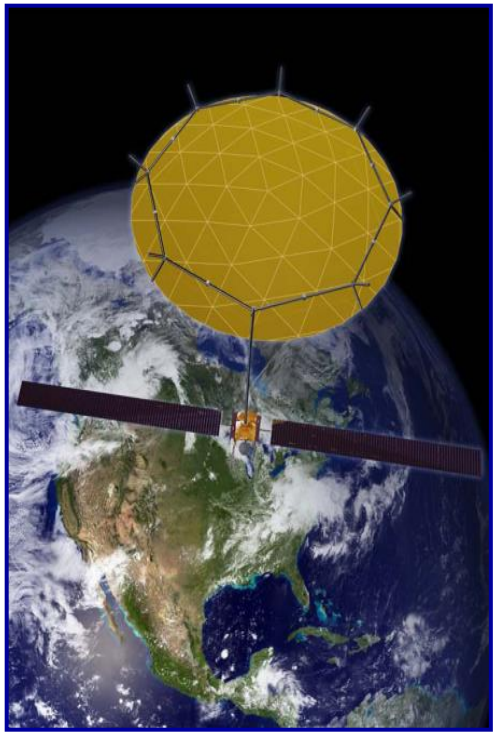
Improved SWx Monitoring
Space Environmental Assessments

Example 1 – Galaxy-15[1]

Orbit: Geosynchronous

Anomaly Date:
05 April 2010 @09:48

Probable Cause:
Internal Charging/ESD

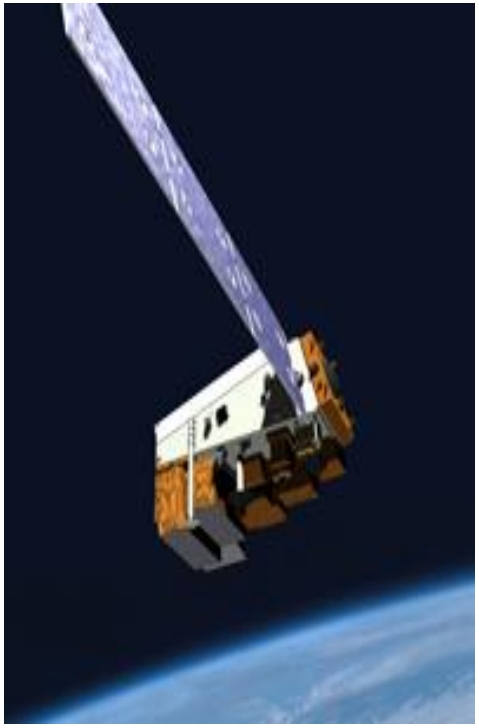


Example 2 – SkyTerra-1

Orbit: Geosynchronous

Anomaly Date:
07 March 2012 @14:43

Probable Cause:
Single-Event Upset



Example 3 – NPP/VIIRS

Orbit: Polar LEO

Anomaly Date:
Various

Probable Cause:
Single-Event Upsets

Solar forcing on Earth's atmosphere is wavelength dependent. Solar extreme ultraviolet (EUV) photons and x-rays are primary energy sources to the upper atmosphere affecting satellite drag, radiowave communications and navigation, and upper atmospheric chemistry.

Poster 660 – SUVI

Automatic Analysis of EUV Solar Features using Solar Imagery for the GOES-R SUVI

Authors: **Jonathan Darnel**, S.M. Hill and W.F. Denig

Coronal Holes are the source of the high-speed solar wind. One of the SUVI L2+ products will automatically determine the boundaries of the coronal holes classified from the Thematic Map product and produce a list of vertices to describe each Coronal Hole. This list of vertices will aid forecasters in the prediction of changes to the solar wind speeds. Other SUVI L2+ products are maps and shapefiles of bright regions and solar flare locations.
